ABOUT A VARIANT OF THE 1d VLASOV EQUATION, DUBBED “VLASOV-DIRAC-BENNEY EQUATION”

CLAUDE BARDOS

ABSTRACT. This is a report on project initiated with Anne Nouri [3], presently in progress, with the collaboration of Nicolas Besse [2] ([2] is mainly the material of this report). It concerns a version of the Vlasov equation where the self interacting potential is replaced by a Dirac mass. Emphasis is put on the relations between the linearized version, the full non linear problem and also on natural connections with several other equations of mathematical physic.

1. INTRODUCTION

This talk was devoted to a one d variant of the classical Vlasov-Poisson equation where the Coulomb interacting potential $V$ is replaced by the delta mass:

$$\partial_t f(t, x, v) + v \partial_x f(t, x, v) - \partial_x \rho_f(t, x) \partial_v f(t, x, v) = 0, \quad \rho_f(t, x) = \int_R f(t, x, v) dv.$$  

Since, in one of the most important configuration it is equivalent to the Benney equation (cf. section and [4]) we call it the Vlasov–Dirac–Benny equation or in short V−D−B.

This equation exhibit both some similarities (at the level of the formal structures) and some basic difference with the system

$$\partial_t f + v \cdot \nabla_x f + E \cdot \nabla_v f = 0, \quad E = -\nabla_x \int_{R^d} V(x - y) \left( \int_{R^d} f(t, y, v) dv - 1 \right) dy$$

generalization (with respect to the potential $V$) of the Vlasov -Poisson equation.

On one hand all the equations of the type (1.2) share in common some essential properties recalled below:

They are “Liouville equations” associated to a dynamical flow defined by the equations

$$\dot{x}(t) = v(t), \quad \dot{v}(t) = -\int_{R^d} \nabla_x V(x(t) - y) \left( \int_{R^d} f(t, y, w) dw - 1 \right) dy.$$  

They (at least formally) conserve the energy

$$\mathcal{E}(f) = \int_{R^d \times R^d} \frac{|v|^2}{2} f(t, x, v) dx dv + \frac{1}{2} \int_{R^d \times R^d \times R^d \times R^d} V(x - y) f(t, x, v) f(t, y, w) dw dy dx dv.$$  

On the other hand when the potential is a Dirac mass the uniform background which is represented by the constant 1 in the definition of the global density $\rho = \int_{R^d} f(t, y, v) dv - 1$, to ensures global neutrality of the plasma can, be removed and the equation becomes:

$$\partial_t f + v \cdot \nabla_x f - \nabla_x \rho_f \cdot \nabla_v f = 0, \quad \rho_f(x, t) = \int_{R^d} f(x, v, t) dv.$$  

Moreover in (1.4) the mapping $f \mapsto \rho_f \mapsto E = -\nabla_x \rho_f$ is an operator of degree 1 while for the original Vlasov-Poisson equation it is an operator of degree −1. Therefore the effect of the instabilities will be much more drastic and while for the original Vlasov-Poisson equation the
issue is the large time asymptotic behavior, here the issue is that the Cauchy problem may be badly posed even for regular initial data and for arbitrarily small time.

Below we focus on the equation (1.1) which is the 1d version of the problem and where instead of the symbol $\nabla$ the symbol $\partial$ is used.

The interest of a one-dimensional space model may be fully justified by physical reasons, particularly in the quasineutral-limit when the Debye length vanishes (cf [14]). Moreover it is in one dimension that the spectral analysis of the linearized problem is, by an adaptation of the method of Penrose (cf [31]), the most explicit. Then, as we try to show, there is a natural connection between the properties of the linearized and the fully nonlinear model. This connection emphasizes the role of “bumps” in the initial profile. In particular in the case of the one-bump profile the connection with the Benney equation gives a new stability theorem for the full nonlinear problem. Eventually the stability results are in full agreement with what is known concerning the WKB limit of the Non-Linear Schrödinger equation.

2. THE MODAL ANALYSIS OF THE LINEARIZED EQUATION

In this section one considers in $\mathbb{R}_x \times \mathbb{R}_v$ the dynamic of the V−D−B equation for fluctuations near the neighborhood of space independent probability distribution function $G(v)$,

$$G(v) \geq 0, \quad \int_{\mathbb{R}} G(v)dv = 1,$$

which is an obvious stationary solution of the equation

$$\partial_t f + v \partial_x f - \partial_x \rho_f \partial_v f = 0, \quad \rho_f(x,t) = \int_{\mathbb{R}_v} f(x,v,t)dv$$

Therefore $f$ is changed into $G(v) + f$ ($f$ denoting now the fluctuations) and the linearized equation becomes

$$\partial_t f + v \partial_x f - \partial_x \rho G'(v) = 0,$$

by dropping quadratic terms in the fluctuations.

2.1. Modal analysis of the linearized equation. A standard tool in the analysis of the general (for any potential $V$) Vlasov equation is the introduction of modal analysis, i.e. solutions (whenever they exist) of the form

$$e_k(t,x,v) = A(k,v)e^{i(kx-\omega(k)t)},$$

leading to the equation

$$(-i\omega(k) + ikv)A(k,v) - ik\hat{V}(k)\hat{\rho}_A(k)G'(v) = 0,$$

which upon integration with respect to $v$ is equivalent to

$$A(k,v) - \hat{V}(k)\frac{G'(v)}{v - \omega(k)/k}\hat{\rho}_A(k) = 0,$$

and

$$\left(1 - \hat{V}(k)\int_{\mathbb{R}} \frac{G'(v)}{v - \omega(k)/k}dv\right)\hat{\rho}_A(k) = 0.$$ 

Instabilities appear whenever there exists a solution $\omega(k)$ of the above system with $\text{Im} \omega(k) > 0$, where $\text{Im}$ denotes the imaginary part. This approach has been developed by Penrose [31] for the one-dimensional Vlasov-Poisson equation where one has $\hat{V}(k) = 1/k^2$. In this case the system (2.1) and (2.2) has no solution for $\text{Im} \omega \neq 0$ and $|k|$ large enough. This is in agreement
with the fact that the problem is always well posed and that the only issues are its asymptotic behavior for $|t|$ going to $\infty$.

Below we adapt the Penrose construction to the linearized V–D–B equation

$$\partial_t f + v \partial_x f - \partial_x \rho_f G'(v) = 0, \quad \rho_f(t,x) = \int_{\mathbb{R}} f(t,x,v) dv. $$

The main difference is that now the operator $f \mapsto \partial_x \rho_f G'(v)$ is “of order 1” while for the Vlasov-Poisson equation it was “of order $-1$” and therefore it supports more violent perturbations.

With $\omega(k) = \omega^* k$ (observe that $\omega^*$ has the dimension of a complex velocity and note the link with the typical dispersion relation for the frequency of acoustic waves $\text{Re} \omega = ck$, with $c$ a real constant velocity) the system (2.1) and (2.2) becomes

$$(2.3) \quad A(k,v) - \frac{G'(v)}{v - \omega} \hat{\rho}_A(k) = 0 $$

and

$$(2.4) \quad \left(1 - \int_{\mathbb{R}_v} \frac{G'(v)}{v - \omega^*} dv \right) \hat{\rho}_A(k) = 0. $$

We now introduce the open sets $\mathcal{S}_\pm = \{ \omega \in \mathbb{C}, \pm \text{Im} \omega > 0 \}$, the mapping

$$Z : \omega \mapsto Z(\omega) = \int_{\mathbb{R}_v} \frac{G'(v)}{v - \omega} dv, $$

and call solutions $\omega$ of the equation

$$Z(\omega) = 1 \quad \text{with} \quad \text{Im} \omega \neq 0, $$

unstable modes. Observe that $\omega \in \mathcal{S}_+$ is a solution of (2.4) if and only $\overline{\omega} \in \mathcal{S}_-$ is also a solution. Therefore it is enough to consider only the set $Z(\mathcal{S}_+)$. As in [31] one has the:

**Proposition 2.1.** Assume for the probability profile $v \mapsto G(v)$ the following regularity hypothesis:

$$(2.5) \quad v \mapsto G'(v) \in C^{0,\alpha}(\mathbb{R}_v) \cap L^1(\mathbb{R}_v). $$

Then the mapping $\omega \mapsto Z(\omega)$ is well defined and analytic on $\mathcal{S}_+$. Moreover $Z(\mathcal{S}_+)$ is a bounded set with boundary given by

$$\partial(Z(\mathcal{S}_+)) = \left\{ w \in \mathbb{R} \mapsto \text{p.v.} \int_{\mathbb{R}_v} \frac{G'(v)}{v - w} dv + i\pi G'(w) \right\};$$

$\partial(Z(\mathcal{S}_+))$ is a bounded curve which go to 0 for $w \to \pm \infty$.

Therefore the existence or non-existence of unstable modes is equivalent to the fact that 1 belongs or not to the set $Z(\mathcal{S}_+)$. Proceeding as in [31] one follows the curve

$$\partial Z_+ : \omega \in \mathbb{R} \mapsto \text{p.v.} \int_{\mathbb{R}_v} \frac{G'(v)}{v - w} dv + i\pi G'(w). $$

This curve starts and ends at the origin for $\omega = \pm \infty$ and winds round $Z(\mathcal{S}_+)$ anticlockwise.

To have $1 \notin Z(\mathcal{S}_+)$ it is sufficient that any $Z(v^*)$ point of intersection of $\partial Z_+$ (whenever it exists) belongs to the interval $]-\infty,1[$. However to have $1 \in Z(\mathcal{S}_+)$ it is necessary (but not sufficient, at variance with the standard Penrose Criteria) that $\partial Z_+$ crosses the real axis at a point $Z_+(v^*) \in [1,\infty)$. This leads to the following
**Theorem 2.1.** Assume for the profile $G$ the regularity hypothesis (2.5) then:

1. If for any solution of $v^* \in \mathbb{R}$ of the equation $G'(v^*) = 0$ one has
   \begin{equation}
   \text{p.v.} \int_{\mathbb{R}} \frac{G'(v)}{v - v^*} dv < 1,
   \end{equation}
   there are no unstable mode.

2. If $G(v)$ has a minimum $v^*$ with the relation
   \begin{equation}
   \text{p.v.} \int_{\mathbb{R}} \frac{G'(v)}{v - v^*} dv > 1,
   \end{equation}
   and no maximum with $v^{**}$ with
   \begin{equation}
   \text{p.v.} \int_{\mathbb{R}} \frac{G'(v)}{v - v^{**}} dv > 1,
   \end{equation}
   there exist unstable modes.

**Proof.** For the proof it is enough to follow the curve $\partial Z_+$ from $\omega^* = -\infty$ to $\omega^* = +\infty$. □

**Remark 2.1.**

1. The above theorem concerns points $v^* \in \mathbb{R}$, where $G'(v^*) = 0$ therefore (with the regularity hypothesis (2.5)), the Cauchy principal values of integrals, denoted by “p.v.”, are in fact classical integrals.

2. For any $\omega^*$ with $\Im \omega^* \neq 0$ the validity of the integration by part
   \begin{equation}
   \int_{\mathbb{R}} \frac{G'(v)}{v - \omega^*} dv = \int_{\mathbb{R}} \frac{G(v)}{(v - \omega^*)^2} dv
   \end{equation}
   implies that the relation (2.4) is well defined not only for profiles in the class $C^{1,\alpha}$ but also for any finite measure. As a consequence the statements of the theorem (2.1) can be extended to more general profiles. For instance if the profile $G$ is the limit in weak $L^1$ of a family of probabilities $G_\epsilon(v) \in C^{1,\alpha}$ satisfying the property:
   \begin{equation}
   \forall \omega^* \in \Im_+ \quad |1 - \int_{\mathbb{R}_v} \frac{G'_\epsilon(v)}{v - \omega^*} dv| > \eta
   \end{equation}
   with $\eta$ independent of $\epsilon$ there are no unstable modes.

As explained in classical books of Plasma Physics (cf. [25] Chapter 9) longitudinal electrostatic kinetic instabilities are related to the effect of “bump-on-tail” in the profile $G(v)$. This is in agreement with the following examples where the existence of unstable modes, is discussed either as illustration of the theorem (2.1) or with direct computations.

**Example 1.** A profile $G(v) \in C^{1,\alpha}$ with only one local maxima (say $v^*$) generates no unstable mode. In fact for the only point where $\partial Z_+$ crosses the real axis is $v^*$ and since $G(v)$ is increasing for $v < v^*$ and decreasing for $v > v^*$ one has
   \begin{equation}
   \int_{\mathbb{R}} \frac{G'(v)}{v - v^*} dv < 0 < 1.
   \end{equation}

**Example 2.** In particular when $G(v) = \delta_v$ is a Dirac mass (the extreme case a one simple bump) of a mass there is no unstable mode. With the point 2 of the remark 2.1 this follows from the point 1 of the theorem 2.1. Moreover this can also be proven by the following explicit computation
   \begin{equation}
   G(v) = \delta_v \implies \int_{\mathbb{R}} \frac{G'(v)}{v - \omega} dv = \int_{\mathbb{R}} \frac{\delta_v}{(v - \omega)^2} dv = \frac{1}{\omega^2}.
   \end{equation}
and therefore the solutions of the dispersion equation $\omega^2 = 1$ (cf. Eq. (2.4)) are given by

$$\omega^* = \pm 1,$$

numbers with no imaginary part.

Example 3. However for $G(v) = \frac{1}{2}(\delta_{v-a} + \delta_{v+a})$ the existence of unstable modes depends on the size of $a$. Dirac masses generate unstable modes, if and only if they are close enough, according to the formula

$$1 - \int \frac{G'(v)}{v - \omega} dv = 1 - \frac{1}{(a - \omega)^2} + \frac{1}{(a + \omega)^2},$$

which has non real solutions if and only if $a^2 < 2$.

Example 4. Assume that $G(v)$ is even with $G(0) = G'(0) = 0$, then for $\epsilon$ small enough,

$$G_\epsilon(v) = \frac{1}{\epsilon} G(v)$$
generates unstable modes. In fact for $\omega^* = i \sigma$ with $\sigma \in \mathbb{R}$ the solution of the equation

$$1 - \int \frac{G'_\epsilon(v)}{v - \omega^*} dv = 0,$$

becomes

$$0 = 1 - \int \frac{G'_\epsilon(v)}{v - \omega^*} dv = 1 - \int \frac{G'_\epsilon(v)}{v^2 + \sigma^2} dv - i \int \frac{G'_\epsilon(v) \sigma}{v^2 + \sigma^2} dv$$

$$= 1 - \int \frac{G'_\epsilon(v)}{v^2 + \sigma^2} dv. \tag{2.9}$$

Eventually the function

$$\sigma \mapsto I(\sigma) = \int \frac{G'_\epsilon(v)}{v^2 + \sigma^2} dv,$$

is continuous decreasing from $I(0) = \int \frac{G'_\epsilon(v)}{v} dv$ to $I(\infty) = 0$ and by continuity the existence of a solution of (2.9) is ensured when

$$\text{p.v.} \int \frac{G'_\epsilon(v)}{v} dv = 2 \int_0^\infty \frac{G'_\epsilon(v)}{v} dv = 2 \int_0^\infty \frac{G'_\epsilon(v)}{v^2} dv = \frac{2}{\epsilon_2} \int_0^\infty \frac{G(v)}{v^2} dv > 1.$$

3. CONSEQUENCE OF THE MODAL ANALYSIS FOR THE LINEARIZED PROBLEM: STABILITY OF THE SINGLE BUMP PROFILE.

In the presence of unstable modes (which are frequency homogenous $\omega(k) = \omega^* k$) the solution of the V–D–B equation with initial data

$$\int e^{ikx} \frac{G'(v)}{v - \omega^*} \hat{\rho}(k) dk,$$

has to be given by

$$f(x, v, t) = \int e^{ikx} e^{-i\omega^* k t} \frac{G'(v)}{v - \omega^*} \hat{\rho}(k) dk,$$

and even for initial data in $\mathcal{S}(\mathbb{R})$ for $t > 0$ it is not defined (even in $\mathcal{S}'(\mathbb{R})$) unless $|\rho(k)| \leq C e^{-a|k|}$. In this case (which corresponds to analytic initial data $[30, 35]$) it exists up to a finite time $T^* = a/|\text{Im}\, \omega^*|$ and may not exist for later time.

On the other hand a profile $v \mapsto G(v)$ with only one maximum leads to a stability result, robust with respect to the potentials and profiles $G(v)$ . To precise the stability result we start with the derivation of a formal energy identity for smooth functions:
Proposition 3.1. Assume that the profile $G(v)$ has only one bump or more precisely that:

\[(3.1) \quad G'(v) := -H(v)(v-a) \quad \text{with} \quad H(v) > 0, \quad a \in \mathbb{R},\]

then any smooth solution $f(x,v,t)$ of the linearized Vlasov equation with potential $V$:

\[(3.2) \quad \partial_t f(t,x,v) + v \partial_x f(t,x,v) - G'(v) \partial_x \int V(x-y) \left( \int f(t,y,w)dw \right) dy = 0,\]

satisfies the energy identity:

\[(3.3) \quad \frac{1}{2} \frac{d}{dt} \left( \int_{\mathbb{R} \times \mathbb{R}} H^{-1}(v)(f(t,x,v))^2 dxdv \right) + \int_{\mathbb{R} \times \mathbb{R}} V(x-y) \rho_f(t,y) \rho_f(t,x) dxdy = 0.\]

Proof. Let us introduce the notation $f(t,x,v) = H(v) \tilde{f}(t,x,v)$, multiply the equation (3.2) by $\tilde{f}$ and integrate over the phase-space $(x,v)$ to obtain

\[(3.4) \quad \frac{1}{2} \frac{d}{dt} \left( \int_{\mathbb{R} \times \mathbb{R}} H^{-1}(v)(f(t,x,v))^2 dxdv \right) + \int_{\mathbb{R} \times \mathbb{R}} \partial_x V(x-y) \rho_f(t,y) \int_{\mathbb{R}} H(v)(v-a) \tilde{f}(t,x,v) dv dy dx = 0.\]

Then observe that one has

\[a \int_{\mathbb{R} \times \mathbb{R}} \partial_x V(x-y) \rho_f(t,y) \int_{\mathbb{R}} f(t,x,v) dv dy dx = a \int_{\mathbb{R} \times \mathbb{R}} \partial_x V(x-y) \rho_f(t,y) \rho_f(t,x) dy dx = 0.\]

Therefore (3.4) turns out to be

\[(3.5) \quad \frac{1}{2} \frac{d}{dt} \left( \int_{\mathbb{R} \times \mathbb{R}} H^{-1}(v)(f(t,x,v))^2 dxdv \right) - \int_{\mathbb{R} \times \mathbb{R}} V(x-y) \rho_f(t,y) \partial_x \int_{\mathbb{R}} v H(v) \tilde{f}(t,x,v) dv dy dx = 0.\]

This last term can be obtained by integration of (3.2) with respect to the velocity $v$ as

\[(3.6) \quad \partial_v \rho_f(t,x) + \partial_x \int_{\mathbb{R}} v H(v) \tilde{f}(t,x,v) dv = 0.\]

Plugging (3.6) into (3.5) one obtains (3.3). \qed

With the above computation in mind we consider linearized Vlasov equations with a semi-definite profile $V$ near a profile $G(v)$ which satisfies the relation

\[(3.7) \quad G'(v) := -H(v)(v-a) \quad \text{with} \quad H(v) > 0, \quad a \in \mathbb{R},\]

and introduce the Hilbert space $\mathcal{H}_V$ of functions $f : \mathbb{R}^2 \mapsto \mathbb{R}$ such that:

\[\int_{\mathbb{R} \times \mathbb{R}} -H_V(v)(f(x,v))^2 dxdv + \int_{\mathbb{R} \times \mathbb{R}} V(x-y) \rho_f(x) \rho_f(y) dxdy < \infty,\]

with the scalar product $\langle \cdot, \cdot \rangle_{\mathcal{H}}$ is defined by

\[\langle f, g \rangle_{\mathcal{H}_V} = \int_{\mathbb{R} \times \mathbb{R}} H^{-1}(v)f(x,v)g(x,v) dxdv + \int_{\mathbb{R} \times \mathbb{R}} V(x-y) \rho_f(x) \rho_f(y) dxdy,\]
Remark 3.1. 1 Since \( G(v) \) is a positive density the weight
\[
H^{-1}(v) = -\frac{(v-a)}{G'(v)},
\]
is unbounded for \(|v| \to \infty\). Therefore \( \mathcal{H}_V \) is a subspace of functions of \( L^2(\mathbb{R}_x \times \mathbb{R}_v) \) with convenient decay for \( v \to \infty \).

2 Semi-definite potentials are potentials \( V \) such that
\[
\int_{\mathbb{R} \times \mathbb{R}} V(x-y) g(x) g(y) dx dy \geq 0
\]
for all continuous functions \( g \) with compact support. By Bochner theorem (cf. Chapter XI, 13 of Yosida [36]) such potential are the Fourier transform of positive measures
\[
V(x) = \int_{\mathbb{R}} e^{i k \tilde{V}(k)},
\]
with \( k \mapsto \tilde{V}(k) \) a non decreasing right-continuous bounded function. This class obviously contain the Dirac mass and in this case the scalar product on \( \mathcal{H}_V \) becomes
\[
\langle fg \rangle_{\mathcal{H}_V} = \int_{\mathbb{R} \times \mathbb{R}} H^{-1}(v) f(x,v) g(x,v) dx dv + \int \rho_f(x) \rho_g(x) dx
\]
For the unbounded operator \( A \) defined as the restriction to \( \mathcal{H}_V \) of the operator:
\[
f \mapsto \nu \partial_x f - \partial_v \int V(x-y) \int f(y,w) dw dy \partial_v f : \quad D(A) = \{ f \in \mathcal{H}_V \text{ s.t.} \nu \partial_x f - \partial_v \int V(x-y) \int f(y,w) dw dy \partial_v f \in \mathcal{H}_V \}
\]
one has the following

**Theorem 3.1.** For semi-definite potential \( V \) and \( G \) a profile which satisfies the relation (3.1) the unbounded operator \( A \) is anti-adjoint in \( \mathcal{H}_V \) and therefore is the generator of a strongly continuous group of unitary operators in this space.

**Proof.** With the energy conservation (3.3) and the access to explicit computation the rest of the proof is routine. First show that \( A \) is closed and anti-adjoint. Therefore for any \( \lambda \in \mathbb{R} - \{0\} \) the image of \( (\lambda I + A) \) is closed subspace of \( \mathcal{H} \). Then in Fourier space solve the equation
\[
\lambda f + Af = g \in S(\mathbb{R}_x \times \mathbb{R}_v),
\]
and observe that the solution of (3.12) belongs to \( D(A) \).

\( (\lambda I + A)(D(A)) \) being both closed and dense coincides with \( \mathcal{H} \). And following Kato [24] page 271 or 279 one completes the proof. \( \square \)

**Corollary 3.1.** With the hypothesis of the theorem (3.1) \( A \) is the generator of a strongly continuous unitary group and the Cauchy problem
\[
\frac{df}{dt} + Af = 0 \quad f(x,v,0) = f_0(x,v)
\]
has for any initial data \( f_0 \in \mathcal{H}_V \) a unique “weak” solution \( f(x,v,t) = (e^{-itA} f_0)(x,v) \in C(\mathbb{R}_t; \mathcal{H}_V) \) Moreover whenever \( f_0 \in D(A) \) this solution is strong (i.e. \( f(.,.,t) \in C^1(\mathbb{R}_t; \mathcal{H}_V) \cap C^0(\mathbb{R}_t; D(A)) \)).
This statement is a direct consequence of the theorem 3.1 in the frame of strongly continuous semi groups and no proof is needed.

**Remark 3.2.** 1 Since \( G(v) \) is a positive density the weight
\[
H^{-1}(v) = - \frac{(v - a)}{G'(v)},
\]
is unbounded for \(|v| \to \infty\). Therefore the corollary 3.1 concerns the evolution of solutions with convenient decay at infinity.

2 The theorem 3.1 has been stated for any Vlasov equation with a semi-positive definite potential. In particular it applies to the case where \( V \) is the Delta distribution.

4. CONSEQUENCE OF THE MODAL ANALYSIS FOR THE NONLINEAR VLASOV-DIRAC-BENNEY EQUATION

The above analysis of the linearized V–D–B equation leads by perturbations method to well adapted instability or stability results for the nonlinear-problem.

For a theorem concerning the instability we denote by \( \dot{H}^m \) the space of functions \( f \in L^\infty(\mathbb{R}_x, L^1(\mathbb{R}_v)) \) with, for \( 1 \leq l \leq m \), derivatives \( \partial_x^l f \in L^2(\mathbb{R}_x; L^1(\mathbb{R}_v)) \) equipped with the corresponding norms.

**Definition 4.1.** We say that a Cauchy problem \( f_0(x, v) \to S(t)[f_0](x, v) \), defined by a nonlinear dynamics on the phase space \((x, v) \in \mathbb{R} \times \mathbb{R} \), is locally \((\dot{H}^m - \dot{H}^1)\) well-posed if there is a constant \( c_m \) such that for any initial datum \( f_0 \in \dot{H}^m \), there exist a time \( T > 0 \) and a unique solution
\[
S(t)[f_0] \in L^\infty(0, T; \dot{H}^1)
\]
such that
\[
\text{ess sup}_{t \in (0, T)} \| S(t)[f_0] \|_{\dot{H}^1} \leq c_m \| f_0 \|_{\dot{H}^m}.
\]

**Theorem 4.1.** For every \( m \in \mathbb{N}^* \), the Cauchy problem for the dynamics \( S(t) \) defined by the V–D–B equation is not locally \((\dot{H}^m - \dot{H}^1)\) well-posed.

**Proof.** The proof follows standard perturbation techniques as developed by [20] and coworkers. It proceeds par contradiction. Assume that the problem is locally \((\dot{H}^m - \dot{H}^1)\) well-posed. Introduce a profile \( G(v) \) which generates unstable modes \( \omega^* k \) and consider, for the dynamics \( S(t) \), initial data of the form
\[
f_0^* = G(v) + s \phi_0(x, v) \quad \text{with} \quad \phi_0(x, v) = \int_\mathbb{R} e^{ikx} \frac{G'(v)}{v - \omega^*} \hat{\rho}(k) dk.
\]

If the nonlinear problem is \((\dot{H}^m - \dot{H}^1)\) well-posed for \( 0 < t < T \) on this interval the function
\[
\partial_s (S(t)[f_0^*])|_{s=0}
\]
belongs to \( L^\infty(0, T; \dot{H}^1) \) and is a solution of the linearized problem. Hence by explicit computation in Fourier space, it has to be given by the formula
\[
\partial_s (S(t)[f_0^*])|_{s=0}(x, v, t) = \int_\mathbb{R} e^{ikx} e^{-\omega^* kt} \frac{G'(v)}{v - \omega^*} \hat{\rho}(k) dk.
\]

If the problem would be well posed, for initial data given by (4.1) with
\[
\forall m > 0 \lim_{|k| \to \infty} |k|^m |\hat{\rho}(k)| = 0 \quad \text{and} \quad \forall a > 0 \lim_{|k| \to \infty} |\rho(k)| e^{a|k|} = \infty
\]
(which belong to $\cap_m \dot{H}^m$) the solution of the linearized problem would exist for some time $T$. But the formula (4.2) shows that this is not possible. Hence the contradiction.

However (4.2) also indicates that, for initial data satisfying the condition

\begin{equation}
|\hat{\rho}(k)| \leq C e^{-a|k|},
\end{equation}

the linearized problem may remain well posed for $|t| < a/|\omega^*|$ and therefore the non linear problem may be also locally in time well posed.

With the Payley-Wiener theorem (cf. [36] p. 161, and [30, 35]) the condition (4.4) implies that the function $\rho(x)$ can be extended as an analytic function $\rho(x + iy)$ in the strip $|y| < a$.

Therefore it is only in the analytic setting that a general Cauchy theorem for the V–D–B equation can be valid and this is the object of the following

**Theorem 4.2. Jabin-Nouri (2011) [22]:** For any $(x, v)$ analytic function $f_0(x, v)$ with

\[ \forall \alpha, m, n \sup_x |\partial_x^m \partial_v^n f_0(x, v)|(1 + |v|)^\alpha = C(m, n) o(|v|) \]

there exists, for a finite time $T$, an analytic solution of the Cauchy problem.

5. RELATIONS WITH FLUID MECHANICS

However as observed above the linearization near a simple bump profile leads to a very stable evolution equation and this motivates several stability theorems. Some of them can be obtained by connections with different equations of fluid mechanics.

5.0.1. The mono-kinetic solution. Direct computations show that a phase space density

\[ f(t, x, v) = \rho(t, x) \delta(v - u(t, x)) \]

is a distributional solution of the V–D–B equation (1.1) if and only if its moments

\[ \rho(t, x) = \int_{\mathbb{R}} f(t, x, v) dv \quad \text{and} \quad \rho(t, x) u(t, x) = \int_{\mathbb{R}} v f(t, x, v) dv \]

are solutions of the system

\begin{equation}
\partial_t \rho + \partial_x (\rho u) = 0, \quad \partial_t (\rho u) + \partial_x \left( \rho u^2 + \frac{\rho^2}{2} \right) = 0.
\end{equation}

For $(\rho, u) \in \mathbb{R}_+ \times \mathbb{R}$ the system is strictly hyperbolic therefore the existence of a local in time (near $(\rho_0, u_0) \in H^2(\mathbb{R})$ with $\rho_0(x) = \alpha > 0$) of smooth is ensured (cf. [13]) . Observe that this result is in full agreement with the stability of example 2 of the section 2.1.

5.0.2. Multi-kinetic solutions. These observations can be generalized to multi-kinetic solutions of the form

\[ f(t, x, v) = \sum_{1 \leq n \leq N} \rho_n(t, x) \delta(v - u_n(t, x)) \]

with $(\rho_n, u_n)$ solutions of the system

\[ \partial_t \rho_n + \partial_x (\rho_n u_n) = 0, \]

\[ \partial_t (\rho_n u_n) + \partial_x \left( \rho_n u_n^2 + \rho_n \sum_{1 \leq \ell \leq N} \rho_{\ell} \right) = 0. \]

However this system is not always hyperbolic and the Cauchy problem is not always locally in time well posed. In particular for $N = 2$ and $(\rho_1, \rho_2, u_1, u_2) = (1, 1, a, -a)$ direct computations...
show that the system is hyperbolic (hence the Cauchy problem is well posed) if and only if $a^2 > 2$. Once again this is in full agreement with the Example 3 of section 2.1.

6. THE ONE-BUMP CONTINUOUS PROFILE AND THE GENUINE BENNEY EQUATION

The very robust stability of linearized Cauchy problem, near a one-bump profile $G(v)$, indicates that similar local in time results should hold for the full nonlinear equation with initial data near a one-bump profile $G(v)$.

As long as $v \mapsto f(t, x, v)$ remains (for $(t, x)$ given a.e.) a one-bump continuous profile, with maximum equal to 1 for simplicity, i.e.

$$\sup_{v \in \mathbb{R}} f(t, x, v) = 1, \quad (t, x) \text{ a.e.},$$

one defines a.e. in $(x, a) \in \mathbb{R} \times [0, 1]$ the functions $v_{\pm}(t, x, a)$ by the formula

$$v_{-}(t, x, a) \leq v_{+}(t, x, a) \quad f(t, x, v_{\pm}(t, x, a)) = a,$$

and recover the one-bump profile $f(t, x, v)$ according to the formula

$$f(t, x, v) = \int_1^0 Y(v_{+}(t, x, a) - v) - Y(v_{-}(t, x, a) - v))da$$

where $Y$ denotes the Heaviside function.

Direct computation shows that in this situation $f$ is a distributional solution of the V−D−B equation if and only if $v_{\pm}(t, x, a)$ are solutions of the system

$$\partial_t v_{\pm} + v_{\pm} \partial_x v_{\pm} + \partial_x \rho = 0, \quad \rho(t, x) = \int_1^0 (v_{+}(t, x, a) - v_{-}(t, x, a))da.$$

If we introduce the mean density and velocity of the fluid labelled by the tag “$a$”, defined respectively by

$$\varrho(t, x, a) = v_{+}(t, x, a) - v_{-}(t, x, a), \quad u(t, x, a) = \frac{1}{2}(v_{+}(t, x, a) + v_{-}(t, x, a))$$

this system (6.2) is equivalent to the fluid type system

$$\partial_t \varrho(t, x, a) + \partial_x (\varrho(t, x, a) u(t, x, a)) = 0,$$

$$\partial_t u(t, x, a) + \partial_x \left( \frac{1}{2} u^2(t, x, a) + \frac{1}{8} \varrho^2(t, x, a) \right) + \partial_x \int_0^1 \varrho(t, x, b)db = 0,$$

which was derived by Benney [4] as a model for water-waves. (This the reason for the name Vlasov-Dirac-Benney). Without the integral term $\partial_x \int_0^1 \varrho(t, x, a)da$ the infinite dimensional system (6.4) would be an infinite system of isentropic Euler equations since all the fluids “$a$” are decoupled. For such systems two types of results are available.

1 In any space dimension with smooth initial data the local in time existence uniqueness and stability of a solution (see [13]).
2 In 1 space variable the existence of a global in time weak entropic solution ([11]).

The proof of 1 relies on the fact that the energy

$$\mathcal{E}(u, \varrho) = \frac{1}{2} \int_{\mathbb{R}} \int_0^1 \left( \varrho(t, x, a) u^2(t, x, a) + \frac{1}{12} \varrho^3(t, x, a) \right) dada$$

is for the isentropic equation (in the sense of Peter Lax) a convex entropy (therefore we use below the name energy-entropy!).
The existence of such entropy implies that the system is hyperbolic. Therefore in 1 space variable it has “Riemann invariants” which are used for the proofs of 2.

In the present case the energy-entropy:

\[
\mathcal{E}(u, \varrho) = \frac{1}{2} \int_{\mathbb{R}} \int_{0}^{1} \left( g(t, x, a) u^2(t, x, a) + \frac{1}{12} \varrho^3(t, x, a) \right) da \, dx + \frac{1}{2} \int_{\mathbb{R}} \left( \int_{0}^{1} g(t, x, a) da \right)^2 dx.
\]

has an extra term which makes the analysis more complicated but does not prevent the generalization of the proofs of 1 or 2.

N. Besse ([5]) already gave a local time result for the Cauchy problem inspired by 2. Using previous works of Teshukov [32, 33, 34] he extended the notion of Riemann invariants as singular integral operators (cf. [5]) for details.

Below we describe a new proof for the system (6.2) inspired by the proofs of results of the type 1. This proof is slightly simpler and requires much less regularity (in particular no regularity with respect to the \( a \) variable).

For a one-bump profile, as above, the conserved energy can be expressed in term of the variables \( v_{\pm} \). With the relation \( f(t, x, v_{\pm}(t, x, a)) = a \) one has

\[
\int_{\mathbb{R}} \frac{|v|^2}{2} f(v) dv = \frac{1}{6} \int_{\mathbb{R}} \frac{dv|^2}{dv} f(v) dv = -\frac{1}{6} \int_{\mathbb{R}} |v|^2 \frac{df}{dv} dv = \frac{1}{6} \int_{0}^{1} (v_+(a) - v_-(a)) da.
\]

Hence for any one-bump profile, using the notation \( \vec{V} = (v_-, v_+) \)

\[
\eta(\vec{V}) = \frac{1}{6} \int_{0}^{1} (v_+(t, x, a) - v_-(t, x, a)) da + \frac{1}{2} \left( \int_{0}^{1} (v_+(t, x, a) - v_-(t, x, a)) \right)^2
\]

is an energy-entropy.

This suggests that the matrix-integral operator (the Hessian of \( \eta(\vec{V}) \))

\[
\Sigma(\vec{V}) = \begin{pmatrix}
-v_-(t, x, a) + \int_{0}^{1} da & -\int_{0}^{1} da \\
-\int_{0}^{1} da & v_+(t, x, a) + \int_{0}^{1} da
\end{pmatrix},
\]

should be a symmetrizer for the system (6.2) in the space \( L^2(\mathbb{R}; L^2(0, 1)) \). Indeed this leads to the

**Proposition 6.1. A priori estimate.** Any smooth solution \( \vec{V} = (v_-, v_+) \) of the equation (6.2), satisfies the a priori nonlinear Gronwall estimate

\[
\frac{d}{dt} \left( \| \vec{V} \|^2_{L^\infty(\mathbb{R} \times (0, 1))} + \| \partial_x \vec{V} \|^2_{L^\infty(\mathbb{R} \times (0, 1))} + \int_{\mathbb{R} \times (0, 1)} (\Sigma(\vec{V}) \partial^3_x \vec{V}, \partial^3_x \vec{V}) da dx \right) \\
\leq C \left( 1 + \| \vec{V} \|^2_{L^\infty(\mathbb{R} \times (0, 1))} + \| \partial_x \vec{V} \|^2_{L^\infty(\mathbb{R} \times (0, 1))} + \| \partial^3_x \vec{V} \|^2_{L^2(\mathbb{R} \times (0, 1))} \right)^2.
\]

**Proof.** The fact that

\[
\forall k \geq 1, \quad | \partial_x^k \rho(t, x) |^2 \leq 2 \int_{0}^{1} | \partial_x^k \vec{V}(t, a, x) |^2 da,
\]

is systematically used. \( C \) denotes different constants, all of them being independent of the solution and changing from line to line. In some of the formulas the variables \((t, x, a)\) may be
omitted. First observe that one has
\[ \|\partial_x^2 \rho\|_{L^\infty(\mathbb{R})} \leq C \left( \|\partial_x^3 \rho\|_{L^2(\mathbb{R})}^2 + \|\rho\|_{L^\infty(\mathbb{R})}^2 \right) \]
\[ \leq C \left( \|\partial_x \bar{V}\|_{L^2(\mathbb{R} \times (0,1))}^2 + \|\bar{V}\|_{L^\infty(\mathbb{R} \times (0,1))}^2 \right). \]
Then from the equation (6.2), using the maximum principle (with integration along characteristic curves), Young inequality and (6.10), one deduce the estimate
\[ \partial_t \|\bar{V}\|_{L^2(\mathbb{R} \times (0,1))} \leq C \left( \|\partial_x \bar{V}\|_{L^\infty(\mathbb{R} \times (0,1))} \|\partial_3 \bar{V}\|_{L^2(\mathbb{R} \times (0,1))} \right). \]

By differentiating with respect to the \( x \) variable the equation (6.2) we get
\[ \partial_t \partial_x v_{\pm} + v_\pm \partial_x (\partial_x v_{\pm}) = -(\partial_x v_{\pm})^2 - \partial_x^2 \rho \]
which, using the maximum principle, Young inequality and (6.10), gives the estimate
\[ \partial_t \|\partial_x \bar{V}\|_{L^\infty(\mathbb{R} \times (0,1))} \leq C \left( \|\partial_x \bar{V}\|_{L^2(\mathbb{R} \times (0,1))} \|\partial_x \bar{V}\|_{L^\infty(\mathbb{R} \times (0,1))} \right) \]
\[ \leq C \left( 1 + \|\bar{V}\|_{L^\infty(\mathbb{R} \times (0,1))} \|\partial_x \bar{V}\|_{L^2(\mathbb{R} \times (0,1))}^2 \right). \]
The next step involves the symmetrization of the equation (6.2) written in the form
\[ \partial_t \bar{V} + M \partial_x \bar{V} = 0, \]
with the matrix-integral operator \( M \) given by the formula
\[ M(t, x, a) = \begin{pmatrix} v_-(t, x, a) - \int_0^1 da & \int_0^1 da \\ -\int_0^1 da & v_+(t, x, a) + \int_0^1 da \end{pmatrix}. \]
For later use observe that the derivatives of \( M \) have the following simple form
\[ \forall k \geq 1, \quad \partial_x^k M(t, x, a) = \begin{pmatrix} \partial_x^k v_-(t, x, a) & 0 \\ 0 & \partial_x^k v_+(t, x, a) \end{pmatrix}. \]
Then for the third-order \( x \)-derivative of \( V \) one has
\[ \partial_t \partial_x^3 \bar{V} + M \partial_x (\partial_x^2 \bar{V}) = R, \]
with
\[ R = -\partial_x^2 M \partial_x \bar{V} - 3 \partial_x^2 M \partial_x^2 \bar{V} - 3 \partial_x M \partial_x^3 \bar{V}, \]
and notice that, with the Gagliardo-Nirenberg interpolation inequality
\[ \forall f \in H^2(\mathbb{R}) \quad \|\partial_x f\|_{L^4} \leq C \|\partial_x^2 f\|_{L^2}^{1/2} \|f\|_{L^\infty}^{1/2}, \]
to bound the term \( \|\partial_x^2 M \partial_x^2 \bar{V}\|_{L^2(\mathbb{R} \times (0,1))} \) one has
\[ \|R\|_{L^2(\mathbb{R} \times (0,1))} \leq C \left( \|\partial_x \bar{V}\|_{L^\infty(\mathbb{R} \times (0,1))} \|\partial_x^2 \bar{V}\|_{L^2(\mathbb{R} \times (0,1))} \right). \]
Next apply to the equation (6.15) the operator (6.8) and observe that for almost \( t \geq 0 \), 
\( K = SM \in L((L^2(\mathbb{R} \times (0,1)))^2) \) is a matrix-integral symmetric operator given by the formula

\[
K = \begin{pmatrix}
-v_x^2 + \int_0^1 da \cdot v_- + v_- \cdot \int_0^1 da & -v_- \cdot \int_0^1 da - \int_0^1 da \cdot v_+ \\
-v_+ \cdot \int_0^1 da - \int_0^1 da \cdot v_- & v_+^2 + \int_0^1 da \cdot v_+ + v_+ \cdot \int_0^1 da
\end{pmatrix}.
\]

For later use observe that the \( t \) derivative of \( \Sigma(\vec{V}) \) and the \( x \) derivative of \( K \) are given by

\[
\partial_t \Sigma(\vec{V}) = \begin{pmatrix}
0 & 0 \\
-x \cdot \partial_x v_+ + \partial_x \rho & 0
\end{pmatrix} = \begin{pmatrix}
v_- \cdot \partial_x v_+ + \partial_x \rho & 0 \\
0 & -v_+ \partial_x v_+ - \partial_x \rho
\end{pmatrix}
\]

\[
\partial_x K = \begin{pmatrix}
-2v_- \partial_x v_- + \int_0^1 da \cdot \partial_x v_+ - \partial_x v_- \cdot \int_0^1 da & -\partial_x v_- \cdot \int_0^1 da - \int_0^1 da \cdot \partial_x v_+ \\
-\partial_x v_- \cdot \int_0^1 da - \int_0^1 da \cdot \partial_x v_+ & 2v_+ \partial_x v_+ + \int_0^1 da \cdot \partial_x v_+ + \partial_x v_+ \cdot \int_0^1 da
\end{pmatrix}
\]

Therefore applying \( \Sigma(\vec{V}) \) to the equation (6.15), and taking the \( L^2(\mathbb{R} \times (0,1)) \)-scalar-product against \( \partial_x^3 \vec{V} \), leads to

\[
\frac{d}{dt}(\Sigma(\vec{V}) \partial_x^3 \vec{V}, \partial_x^3 \vec{V}) = 2(\Sigma(\vec{V})R, \partial_x^3 \vec{V}) + (\partial_t \Sigma(\vec{V}) \partial_x^3 \vec{V}, \partial_x^3 \vec{V}) + (\partial_x K \partial_x^3 \vec{V}, \partial_x^3 \vec{V}).
\]

The three terms of the right hand side of (6.19) are estimated as follows. For the first term, using (6.8) and (6.16) one has

\[
\left\| (\Sigma(\vec{V})R, \partial_x^3 \vec{V}) \right\| \leq \left\| \Sigma(\vec{V}) \right\|_{L^\infty} \left\| R \right\|_{L^2(\mathbb{R} \times (0,1))} \left\| \partial_x^3 \vec{V} \right\|_{L^2(\mathbb{R} \times (0,1))}
\]

\[
\leq C(1 + \left\| \partial_x \vec{V} \right\|_{L^\infty(\mathbb{R} \times (0,1))}) \left\| R \right\|_{L^2(\mathbb{R} \times (0,1))} \left\| \partial_x^3 \vec{V} \right\|_{L^2(\mathbb{R} \times (0,1))}
\]

\[
\leq C \left( 1 + \left\| \vec{V} \right\|_{L^\infty(\mathbb{R} \times (0,1))}^2 + \left\| \partial_x \vec{V} \right\|_{L^\infty(\mathbb{R} \times (0,1))}^2 + \left\| \partial_x^3 \vec{V} \right\|_{L^2(\mathbb{R} \times (0,1))}^2 \right)^2.
\]

For the second term, using (6.17) and (6.10), one gets

\[
\left\| (\partial_t \Sigma(\vec{V}) \partial_x^3 \vec{V}, \partial_x^3 \vec{V}) \right\| \leq C \left( \left\| \vec{V} \partial_x \vec{V} \right\|_{L^\infty(\mathbb{R} \times (0,1))} + \left\| \partial_x \rho \right\|_{L^\infty(\mathbb{R})} \right) \left\| \partial_x^3 \vec{V} \right\|_{L^2(\mathbb{R} \times (0,1))}^2
\]

\[
\leq C \left( 1 + \left\| \vec{V} \right\|_{L^\infty(\mathbb{R} \times (0,1))}^2 + \left\| \partial_x \vec{V} \right\|_{L^\infty(\mathbb{R} \times (0,1))}^2 + \left\| \partial_x^3 \vec{V} \right\|_{L^2(\mathbb{R} \times (0,1))}^2 \right)^2.
\]

Finally for the third term, using (6.18) and the same token, one obtains

\[
\left\| (\partial_x K \partial_x^3 \vec{V}, \partial_x^3 \vec{V}) \right\| \leq \left\| \partial_x K \right\|_{L^\infty(\mathbb{R} \times (0,1))} \left\| \partial_x^3 \vec{V} \right\|_{L^2(\mathbb{R} \times (0,1))}^2
\]

\[
\leq C \left( 1 + \left\| \vec{V} \right\|_{L^\infty(\mathbb{R} \times (0,1))}^2 + \left\| \partial_x \vec{V} \right\|_{L^\infty(\mathbb{R} \times (0,1))}^2 + \left\| \partial_x^3 \vec{V} \right\|_{L^2(\mathbb{R} \times (0,1))}^2 \right)^2.
\]

With the insertion of these three estimates in (6.19), and estimates (6.11)-(6.12) the proof of the proposition (6.1) is completed. \( \square \)

This leads to the following theorem

**Theorem 6.1.** Let us introduce the functional space

\[
B(T^\ast) = \left\{ \vec{V} \in C(0, T^\ast; L^\infty(\mathbb{R}_x \times (0,1))) \cap L^\infty(0, T^\ast; L^2((0,1); H^3(\mathbb{R}_x))) \right\}
\]

and the open subset \( \mathcal{O}(m, M, T^\ast) \) of \( B(T^\ast) \), defined by

\[
\mathcal{O}(m, M, T^\ast) = \left\{ \vec{V} \in B(T^\ast) \text{ with } 0 < m < -v_-(t, x, a), v_+(t, x, a) < M < \infty \right\}.
\]
1. Assume that the initial data $\mathbf{\tilde{V}}(0,x,a) = (v^-(0,x,a), v^+(0,x,a))^t$ satisfy for some given $m > 0$, and $M > 0$ the estimate
\begin{equation}
(6.22) \quad m < v^-(0,x,a) < M \quad \text{and} \quad m < v^+(0,x,a) < M,
\end{equation}
and the regularity property
\begin{equation}
(6.23) \quad \|\partial^3_x \mathbf{\tilde{V}}(0)\|_{L^2(\mathbb{R} \times (0,1))} \leq \kappa < \infty,
\end{equation}
then there exists a time $T^* = T^*(m, M, R)$ such that the corresponding Cauchy problem, for the system
\begin{equation}
(6.24) \quad \partial_t v_+ + \partial_x \left( \frac{v^2_+}{2} + \int_0^1 (v^+(t,x,a) - v^-(t,x,a)) da \right) = 0,
\end{equation}
has a unique solution $\mathbf{\tilde{V}} = (v^-(t,x,a), v^+(t,x,a))^t \in \mathcal{O}(m, M, T^*)$.

2. Moreover if $\mathbf{\tilde{V}}(0,x,a)$ is the weak limit (for instance in $L^\infty(\mathbb{R} \times (0,1))$ weak-*) of a sequence of functions $\mathbf{\tilde{V}}^N(t,x,a)$ which satisfy uniformly with respect to $N$ the estimates (6.22) and (6.23) the corresponding solutions (defined in $\mathcal{O}(m, M, T^*)$ with $T^*$ independent of $N$) converge (for instance in $B(T^*)$ weak-*) to a function $\mathbf{\tilde{V}}(t,x,a)$ which is the solution of the problem (6.24) with the corresponding initial data.

Proof. The a priori estimate (6.9) is an adaptation to the present case (where $M$ includes in its expression integral operators) of the classical estimates for hyperbolic systems with entropy. Then the remaining part of the proof follows the lines of this classical case (see [13] for example). The main detail in the difference appears in the Gronwall estimate deduced from the relation (6.9). It would be of the type
\[
\frac{dY}{dt} \leq CY^2,
\]
with
\[
Y(t) = \|\mathbf{\tilde{V}}(t)\|_{L^\infty(\mathbb{R} \times (0,1))}^2 + \|\partial_x \mathbf{\tilde{V}}(t)\|_{L^\infty(\mathbb{R} \times (0,1))}^2 + \int_{\mathbb{R} \times (0,1)} (S(t)\partial^3_x \mathbf{\tilde{V}}(t), \partial^3_x \mathbf{\tilde{V}}(t)) da dx,
\]
if the right hand side of (6.9) could be bounded by $CY^2$. In $Y(t)$ appears the expression
\begin{equation}
(6.25) \quad \Sigma(\mathbf{\tilde{V}}(t))\partial^3_x \mathbf{\tilde{V}}(t), \partial^3_x \mathbf{\tilde{V}}(t))
\end{equation}
\[
= \int_{\mathbb{R}} dx \int_0^1 da \left( -v_-(t,x,a)(\partial^2_x v^-(t,x,a))^2 + v_+(t,x,a)(\partial^2_x v^+(t,x,a))^2 \right)
+ \int_{\mathbb{R}} dx \left( \int_0^1 (\partial^2_x v^+(t,x,a) - \partial^2_x v^-(t,x,a)) da \right)^2,
\]
which is non negative provided $-v^-(t,x,a) > 0$ and $v^+(t,x,a) > 0$. Moreover for $Y(t)$ to be finite at $t = 0$, the hypothesis $-v^-(x,a,0), v^+(x,a,0) < M$ are required. However the relations
\[
m < m_1 < -v^-(t,x,a), v^+(t,x,a) < M_1 < M,
\]
are “open properties” and with $\partial_\Sigma(\mathbf{\tilde{V}})$ bounded in $L^\infty$, they remain valid for a finite time. With these observations one can construct say by iteration and for $T^*$ small enough (as in [13] and [29]) the solution $\Sigma(\mathbf{\tilde{V}}) \in \mathcal{O}(m, M, T^*)$.

The point 2 is a direct consequence of the fact that the $x$ regularity estimate is uniform with respect to $N$. This is enough to pass to the limit in the equations. \qed
Remark 6.1. 1. As noticed above the system, (6.2) is equivalent with the change of unknowns (6.3) to the Benney equation (6.4), hence the theorem 6.1 provides with this change of variables a similar treatment of the Cauchy problem for this system. In fact a direct proof (with slightly more complicated estimates) could be done for this system using the symmetrizer

\[ \nabla^2 \mathcal{E}(\rho, u)(t, x, a) = \left( \frac{1}{4} \rho(t, x, a) + \int_0^1 da \ u(t, x, a) \right) \].

2. The essential “geometric hypothesis” are

\[-M < v_-(x, a, 0) < -m < 0 < m < v_+(x, a, 0) < M.\]

Besides this requirement the present proof uses no regularity or monotonicity of the map \( a \mapsto v_\pm(t, x, a). \) However with the equation

\[ \partial_t \partial_a (v_\pm) + \partial_x (\partial_a (v_\pm)) = 0, \]

obtained by differentiating (6.24) with respect to the \( a \) variable, one observes that the solution \( v_\pm(t, x, a, t) \) given by the theorem 6.1 would preserve the monotonicity of the functions \( a \mapsto v_\pm(t, x, a) \) up to the time \( T^* \) whenever such property holds for \( t = 0 \) [12].

Keeping in mind the point 2 of the above remark one can consider for \( V(t, x, a) \) piecewise constant functions with respect to the \( a \) variable as described in the following,

**Proposition 6.2.** Assume that the functions \( v_\pm(0, x, a) \) are piecewise constant and defined by

for \( 1 \leq j \leq N \) and \( \frac{N - j}{N} < a \leq \frac{N - j + 1}{N} \), \( v_\pm(0, x, a) = v_\pm(0, x, j) \),

with for \( 1 \leq j \leq N \),

\( v_\pm(0, x, j) \in H^3(\mathbb{R}) \) and \( m < -v_-(0, x, j), v_+(0, x, j) < M \),

then the Cauchy problem associated to the waterbag equation (6.24) with the corresponding initial data \( v_\pm(0, x, a) \) has a unique solution \( V \in \mathcal{O}(m, M, T^*) \).

This proposition is a direct consequence of the Theorem 6.1 because the initial data satisfy the hypothesis of this theorem.

To conclude this section the above results are applied to the original Vlasov-Dirac-Benney equation with the following

**Theorem 6.2.** Assume that the functions \( v_\pm(0, x, a) \) satisfy the hypothesis of the Theorem 6.1, that \( a \mapsto v_-(0, x, a) \) is increasing and \( a \mapsto v_+(0, x, a) \) is decreasing then the Vlasov-Dirac-Benney equation (1.1) with initial data given by

\[ f_0(x, v) = \int_0^1 (Y(v_+(0, x, a) - v) - Y(v_-(0, x, a) - v)) da, \]

(with \( Y \) denoting the Heaviside function) has for \( 0 < t < T^* \) a unique solution

\( f(t, x, v) \in L^\infty(0, T^*; L^p(\mathbb{R}_x \times \mathbb{R}_v)) \) for all \( 1 \leq p \leq \infty \),

with

\( \rho(t, x) = \int_{\mathbb{R}} f(t, x, v) dv \in L^\infty(0, T^*; H^3(\mathbb{R})) \),

XV–15
which is given by the formula
\[(6.29)\quad f(t,x,v) = \int_0^1 (Y(v_+(t,x,a) - v) - Y(v_-(t,x,a) - v)) da.\]

Moreover when \( f_0 \) is defined as the limit for \( N \to \infty \) of a sequence of functions
\[f_N^0(x,v) = \int_0^1 (Y(v_+^N(0,x,a) - v) - Y(v_-^N(0,x,a) - v)) da,\]
where the \( a \mapsto v_+^N(0,x,a) \) are monotonic functions \( a \mapsto v_-(0,x,a) \) non-decreasing and \( a \mapsto v_+(0,x,a) \) non-increasing) satisfying, uniformly with respect to \( N \), the hypothesis
\[-M < v_-^N(0,x,a) < -m, \quad 0 < m < v_+^N(0,x,a) < M, \quad \|v_\pm^N(0)\|_{L^2([0,1];H^3(\mathbb{R}))} < \infty,\]
the corresponding solutions exist on a time interval \( T^* \) independent of \( N \) and one has
\[f_N(t,x,v) \to f(t,x,v) \quad \text{in} \quad L^\infty(0,T^*;L^p(\mathbb{R} \times \mathbb{R}_v)) \quad \text{weak-*},\]
\[\rho_N(t,x) = \int_\mathbb{R} f_N^N(t,x,v) \to \rho(t,x) = \int_\mathbb{R} f(t,x,v) dv \quad \text{in} \quad L^\infty(0,T^*;H^3(\mathbb{R})) \quad \text{weak-*} .\]

**Proof.** We first prove that the monotonicity of the functions \( a \mapsto v_\pm(t,x,a) \) is preserved by the dynamics. Let us set \( w_\pm = v_\pm(b) - v_\pm(a) \), \( \bar{v} = v_\pm(b) + v_\pm(a) \), and form the equation for the difference \( w_\pm \) of two solutions of (6.24), which is equivalent to integrate the equation (6.27) with respect to the \( a \) variable between \( a \) and \( b \). Therefore multiplying the resulting equation by the derivative of a convex regularization of the modulus of \( w_\pm \), integrating with respect to the \( x \) variable and using the fact that \( v_\pm(t) \in L^1((0,1);W^{1,1}(\mathbb{R}_x)) \) (since \( v_\pm(t) \in L^2((0,1);H^3(\mathbb{R}_x)) \) and using Sobolev embeddings) we can show the property
\[(6.30)\quad \frac{d}{dt}\|w_\pm\|_{L^1(\mathbb{R}_x)} \leq 0.\]

Now using Crandall-Tartar result [12] about the relation between nonexpansive (i.e. (6.30)) and order preserving (i.e. monotonicity of the functions \( a \mapsto v_\pm(t,x,a) \)) mappings, we get, after time integration of (6.30), the desired result. Since now the monotonicity of the functions \( a \mapsto v_\pm(t,x,a) \) is preserved by the dynamics, it implies that one can use the formula (6.29) to reconstruct the solution \( f \) or \( f^N \). In particular observe that the \( f^N \) are solutions of a Liouville equation
\[\partial_t f^N + v_\partial_x f^N + \partial_x \rho^N \partial_v f^N = 0, \quad \rho^N(t,x) = \int_\mathbb{R} f^N(t,x,v) dv,\]
with \( \rho^N \) uniformly bounded in \( L^\infty(0,T;H^3(\mathbb{R})) \) which can be used to consider the limit \( N \to \infty \).

**Remark 6.2.** The biggest constraint in the above construction is the fact that the functions \( a \mapsto v_\pm(0,x,a) \) have to be defined on a fixed interval (say \( a \in [0,1] \)) and bounded above and below. This implies for the initial profiles \( v \mapsto f_0(x,v) \) the following \( x \) independent properties. (H1) There exist an \( x \) independent constant \( 0 < M < \infty \) such that
\[(6.31)\quad |v| \geq M \Rightarrow f_0(x,v) = 0 \]
(H2) There exist an \( x \) independent constant \( 0 < m < \infty \) constant such that
\[(6.32)\quad |v| \leq m \Rightarrow f_0(x,v) = 1 \]
(H3) \( v \mapsto f_0(x, v) \) is non decreasing on the interval \( (-\infty, y-m] \) and on increasing on the interval \([m, \infty) \mapsto f_0(x, v) \). In short it is a "plateau" profile.

The instability theorem 4.1 implies that the one bump shape of the profile has to be preserved by the dynamic and therefore the hypothesis (H2) and (H3) seem almost optimal. On the other hand in the right hand side of (6.25) appears the \( \partial_3^2 \nabla \) quadratic term

\[
\int_{\mathbb{R}} dx \int_0^1 da \left( -v_-(t, x, a)(\partial_3^2 v_-(t, x, a))^2 + v_+(t, x, a)(\partial_3^2 v_+(t, x, a))^2 \right)
\]

where \( \partial_3^2 v_\pm(t, x, a))^2 \) are multiplied by the factor \(|v_\pm(t, x, a)|\). Therefore with estimates adapted to this factors (treated as weights) it may be possible to relax the hypothesis (H1) and consider one bump initial profiles with unbounded support?

On the other hand it is important to observe that no other regularity with respect to \( v \) is needed and the introduction of the \( v_\pm \) satisfying the hypothesis of the theorem 6.2 shows the validity of the waterbag model (cf. [5] and [6] for details) as a convenient approximation for the continuous model.

Remark 6.3. Some different physical scalings lead, instead of \( V-D-B \) equation, to other variants and in particular to the constant density Vlasov equation, i.e.

\[
\partial_t f + v \cdot \nabla_x f + E \cdot \nabla_v f = 0, \quad \int_{\mathbb{R}^d} f(t, x, v) dv = 1,
\]

(cf. [7, 8, 9, 19, 21]) where the electric field plays the role of the Lagrange multiplier of the constraint "constant density". For instance, in more than one dimension \( (d > 1) \) this equation has non trivial mono-kinetic solutions \( f(t, x, v) = \rho_0 \delta(v - u(t, x)) \), where \( \rho_0 \) is constant and \( u(t, x) \) is the solution of the incompressible Euler equation. For \( d = 1 \), Grenier [19] proves an instability theorem (Theorem 1.1) which is the counterpart of Example 4 of section 2 and of Theorem 4.1 of section 4. Moreover by energy methods he has proven, for one-bump profile a stability result (Theorem 2.1) which share much in common with the present Theorem 6.1.

7. The Vlasov-Dirac-Benney equation at the cross road of semi-classical limits, fluid mechanics and integrability

It has been observed that stability results can be consequences of the relation of the Vlasov equation with equations in fluid mechanics. For the classical Vlasov equation this is not a new idea. Since the paper of Brenier [7] this point of view appeared to be very fruitful for the analysis of singular limits cf. [21], [28], [5] and [6]. However for what we dubbed \( V-D-B \) the connection was already formally made by Zakharov in 1980 [37]. He observed formal relations between the Vlasov equation, and the WKB or semi-classical limits of the Non-Linear Schrödinger equation.

Therefore I would like to emphasize that such formal semi-classical limits turn out to be "rigorously proven limits" only in cases which also correspond to the stability near one-bump profile.

Start from the Schrödinger equation in \( \mathbb{R}^d \) with a time-dependent potential \( V(t, x) \)

\[
(7.1) \quad i\hbar \partial_t \psi = \mathcal{H}(\hbar, V(t))\psi = -\frac{\hbar^2}{2} \Delta \psi + V(t, x)\psi,
\]

which defines a unitary dynamic in \( L^2(\mathbb{R}^d) \) and assume that the wave-function \( \psi \) satisfies the normalization condition

\[
\int_{\mathbb{R}^d} |\psi(t, x)|^2 dx = 1.
\]
With

\[ V(t, x) = \int_{\mathbb{R}^d} \mathcal{V}(x - y)|\psi(t, y)|^2 dy, \]

one has the family of self-consistent Schrödinger equations with in particular the Schrödinger Poisson equation when \( \mathcal{V} \) is the Coulomb Potential or the Non-Linear Schrödinger equation when \( \mathcal{V} \) is the Dirac mass.

On the other hand with the introduction of the commutator \( [A, B] = AB - BA \), the so-called self-consistent von Neumann equation

\[ i\hbar \partial_t K_\hbar(t) = [K_\hbar(t), \mathcal{H}(\hbar, V(t))] \]

defines a dynamics on trace 1 self-adjoint unitary operators in \( L^2(\mathbb{R}^d) \) (with kernel denoted by \( K_\hbar(t, x, y) \)). In particular whenever \( \psi_\hbar(t) \) is solution of the equation (7.1) with \( V(t) \) given by (7.2), \( K_\hbar(t, x, y) = \psi_\hbar(t, x) \otimes \overline{\psi_\hbar(t, y)} \) is a solution of the von-Neumann equation (7.3).

Eventually introduce the Wigner transform of the operator

\[ W_\hbar(t, x, v) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} e^{-iyv} K_\hbar\left(t, x + \frac{\hbar}{2} y, x - \frac{\hbar}{2} y\right) dy, \]

and observe that its formal \( \hbar \to 0 \) limit \( W(t, x, v) \) is a solution of the Vlasov equation

\[ \partial_t W(t, x, v) + v \cdot \nabla_x W(t, x, v) - \nabla_x \left( \int_{\mathbb{R}^d} \mathcal{V}(x - y) \int_{\mathbb{R}^d} W(t, y, w) dw dy \right) \cdot \nabla_v W(t, x, v) = 0, \]

with

\[ W_0(x, v) := W(0, x, v) = \lim_{\hbar \to 0} W_\hbar(0, x, v). \]

Such results are proven when the potential \( \mathcal{V} \) is smooth enough (cf. [27] or [16]).

For the Non-Linear Schrödinger equation and for its formal limit the \( \mathcal{V} - \mathcal{D} - \mathcal{B} \) equation the situation is completely different. Since the Cauchy problem may be ill posed (cf. Theorem 4.1) there are in general no chances of such convergence (even for \( C^\infty \) data and small time).

However, for \( d = 1 \), convergence should hold for initial data of the form

\[ K_\hbar(0, x, y) = \int_{\mathbb{R}} e^{\frac{x+y}{2}} W_0\left(\frac{x+y}{2}, v\right) dv, \]

with \( W_0(x, v) \) being a one-bump profile satisfying in term of \( v_\pm(0, x, a) \) the hypothesis of the Theorem 6.1 because the limit problem is well posed. I am not aware of such result. On the other hand if \( W_0 \) (cf. (7.5)), is analytic (satisfying the Jabin-Nouri hypothesis [22]) convergence should hold for a finite time. Here also, to the best of my knowledge there is no general proof of this fact. However in the WKB limit there is a contribution of P. Gerard [15] which may be generalized. This WKB limit refers to the \( \hbar \) scaling of the equation (as above) and to initial data in the form

\[ \psi_\hbar(0, x) = \sum_{1 \leq k \leq N} \rho_k(x) e^{\frac{S_k(x)}{\hbar}} \]

which give for the Wigner transform at time \( t = 0 \),

\[ W_\hbar(0, x, v) = \frac{1}{2\pi} \int_{\mathbb{R}} e^{-ivy} \psi_\hbar\left(0, x + \frac{\hbar}{2} y\right) \overline{\psi_\hbar\left(0, x - \frac{\hbar}{2} y\right)} dy. \]
Now under general hypothesis \((\rho_k \in L^1_{\text{loc}}, \partial_x S_k \in W^{1,1}_{\text{loc}})\) and the \(\partial_x S_k(x)\) linearly independent one has

\[
W_\hbar(0, x, v) \to \sum_{1 \leq k \leq N} \rho_k(x) \delta(v - \nabla S_k(x)), \quad \text{in } \mathcal{D}'(\mathbb{R}).
\]

For \(N = 1\), this corresponds to a mono-kinetic initial data. This is a case (also the “extreme case” of the one-bump profile) of initial data which give for V–D–B equation a local in time (before the appearance of singularities) stable solution. Therefore in this setting one can expect that the Wigner transform of \(\psi_\hbar(t, x) \otimes \psi_\hbar(t, y)\) will converge to the solution of V–D–B equation. And in fact several proofs of such convergence are available (as said above [15] in the analytic case) but also Grenier [17, 18] with a proof based on a modification of the Madelung transform and finally Jin, Levermore and McLaughlin [23].

Note also that the case \(N > 1\), in formula (7.6), has been considered by Zakharov [37] with formal proofs of convergence. These proofs should completely work in the analytic case as an application of [15]. In less regular cases for example with \(N = 2\) and (7.7) the examples of section 5.0.2 lead to the conjecture that with non analytic initial data, local in time convergence may hold in some cases but not in every cases.

The proof in ([23]) which holds for the mono-kinetic limit is based on the complete integrability of the Non-Linear Schrödinger equation by inverse scattering. And therefore the V–D–B equation appears to share many properties of integrable systems. Zakharov [37] says “it is integrable in a certain sense”! And he insists on the existence, for the genuine Benney equation of an infinite number of integrals of motion obviously related to the infinite set of invariants for the nonlinear Schrödinger equation and to the infinite set of conserved quantities (entropy) for the \(2 \times 2\)-equations of fluid mechanics.

8. Conclusion

The spectral analysis share much in common with the approach of Penrose (because of the \(1d\) structure and of the fact that the potential is semi-positive). However due to the singularity the effect of the initial data on the behavior of the solution (both for the linearized problem and for the original nonlinear equation ) are much more drastic than for the classical Vlasov Poisson equation. The case where the problem is locally in time well posed are treated thanks to interpretation in term of fluid mechanic. A good reason for the name “Benney”.

As said above the stability results are very sensitive to the geometrical structure of the initial data and this sensitivity persists all over the article from the property of the linearized problem to the stability analysis of the non linear one and to its interpretation as a WKB limit of non linear Schrödinger type equations.

What we dubbed energy-entropy quantities are in fact invariants of the dynamic. They could be related at every level of the analysis to an intrinsic hamiltonian structure of the problem and play the same role as the Casimir in the stability theory of Arnold for the \(2d\) Euler equation cf for instance [1].

Therefore this leaves some room for further studies both on one hand for application to approximation and numerical analysis and on the other hand, at intrinsic mathematical theory, for the role that this type of equation may play at the cross road of different limits that share in common some hamiltonian structure. Eventually one may consider perturbation of profiles.
G(v) with “multi-bumps” but small enough so that there would be no unstable mode:

\[
\forall \omega^* \in \mathfrak{H}_+ \quad |1 - \int_{\mathbb{R}_+} \frac{G'(v)}{v - \omega^*} dv| > \eta
\]

In this case one can describe the evolution of the linearized problem (near this profile) by a distribution group of operators as described in [3]. This means a “almost well posed Cauchy problem” or more precisely an evolution equation well posed with a finite lost of regularity. In the setting it may be possible that the non linear problem be approached with the Nash Moser theorem. Such a construction seems to require not only more regularity with respect to the x variable but also to the v. And this type of hypothesis are definitely not satisfied for approximations like the multi water-bags considered above.
